Data Analytics CS301 Multiple Linear Regression Understanding the Summary

Week 11: 10th November Fall 2020 Oliver BONHAM-CARTER

Up To Now in Regression

- We have discussed how one entity influences another.
- What about having two entities (independent) which may have some kind of influence on a dependent variable.
- Especially if a dependent variable has a high correlation with more multiple independent variable.

Main Idea

- GPA could be dependent on studying
- Student performance may be based on more than just one entity.
- GPA could be dependent on studying AND getting enough rest
- OR maybe even more variables are involved?
- GPA could be dependent on studying AND rest AND eating good food AND ...

So, Multiple Linear Regression Is What ...?

- Multiple linear regression is the most common form of linear regression analysis.
- A predictive analysis, the multiple linear regression is used to explain the relationship between one continuous dependent variable and two or more independent variables.
- The independent variables can be continuous or categorical (dummy coded as appropriate).

Types of Questions Answered

- Do age and IQ scores effectively predict GPA?
- Do weight, height, and age explain the variance in cholesterol levels?
- Are video game sales explained by their exciting graphics and inexpensive costs?
- Is road safety a combination of relaxed and defensive driving?
- Are there more independent variables to be used to answer to these above dependents?

Equation of Multiple Independent Variables

The model is now a multi-independent variable equation.

Dependent Variable

 y_i

$$= \beta_0 + \beta_1 x_{i,1} + \beta_2 x_{i,2} + \beta_3 x_{i,3} + \epsilon_i$$

Independent Variables

• A population model for a multiple regression model that relates a y-variable to p-1 predictor variables is written as the following.

$$y_i = \beta_0 + \beta_1 x_{i,1} + \beta_2 x_{i,2} + ... + \beta_{p-1} x_{i,p-1} + \varepsilon_i$$

- We assume that the ε_i have a normal distribution with mean 0 and constant variance σ^2 . These are the same assumptions that we used in simple regression with one x-variable.
- The subscript *i* refers to the ith individual or unit in the population. In the notation for the *x*-variables, the subscript following *i* simply denotes which *x*-variable it is.

Same Hypothesis as Before...

As an example, to determine whether variable X_1 is a useful predictor variable in a model, we use the following hypothsis:

$$H_0: \beta_1 = 0$$

$$H_A : \beta_1 != 0$$

(think slope values)

If the null hypothesis above were the case, then a change in the value of X_1 would not change Y, so Y and X_1 are not related.

We would still be left with variables X_2 and X_3 being present in the model and so we could not reject the null hypothesis above. Instead we should say that we do not need variable X_1 in the model given that variables X_2 and X_3 will remain.

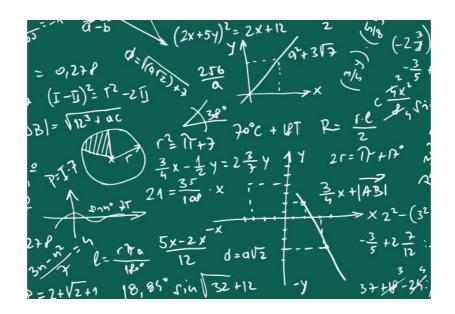

In general, the interpretation of a slope in multiple regression can be tricky. Correlations among the predictors can change the slope values dramatically from what they would be in separate simple regressions.

Analysis Question

- Two variables: Do Age and Height (both) influence the capacity of lungs (LungCap)?
- Asking actually, can we make a model that takes the following form?

LungCap = Age*
$$b_1$$
 + Height* b_2 + b_3

Lung Capacity Data

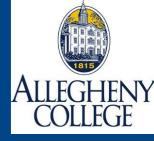

```
library(tidyverse)
# install.packages("psych")
library(psych)
#open lung capacity data
lc <-file.choose()</pre>
dataLungCap <- read.csv(lc)</pre>
View(dataLungCap)
```

```
# model creation
mod <- Im(data = dataLungCap, LungCap ~ Age +
Height)
# get a report of the model
summary(mod)</pre>
```

Summary

```
Call:
lm(formula = LungCap \sim Age + Height)
Residuals:
          1Q Median 3Q
   Min
                            Max
-3.4080 -0.7097 -0.0078 0.7167 3.1679
Coefficients:
           Estimate Std. Error t value Pr(>|t|)
(Intercept) -11.747065   0.476899 -24.632   < 2e-16 ***
        Age
           Height
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
Residual standard error: 1.056 on 722 degrees of freedom
Multiple R-squared: 0.843, Adjusted R-squared: 0.8425
```

Intercept Value:

"When the age and height of zero"

Call:

 $lm(formula = LungCap \sim Age + Height)$

Residuals:

Min 1Q Median 3Q Max -3.4080 -0.7097 -0.0078 0.7167 3.1679

The estimated mean lung capacity of someone having an age and height of zero. Is this *meaningful*?

Coefficients:

Estimate Std. From t value Pr(>|t|)

(Intercept) -11.747065 0.476899 -24.632 < 2e-16 ***

Age 0.126368 0.017851 7.079 3.45e-12 ***

Height 0.278432 0.009926 28.051 < 2e-16 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 1.056 on 722 degrees of freedom

Multiple R-squared: 0.843, Adjusted R-squared: 0.8425

"How is my *Age* variable related to *Height*?"

Call:

 $lm(formula = LungCap \sim Age$

Residuals:

Min 1Q Median -3.4080 -0.7097 -0.0078

The effect of Age on Lung Capacity adjusting or controlling for Height. We may associate an increase of 1 year in Age with an increase of 0.126 in Lung Capacity adjusting or controlling for Height

Coefficients:

Estimate Std ror t value Pr(>|t|)

(Intercept) -11.747065 0.476899 -24.632 < 2e-16 ***

Age 0.126368 0.017851 7.079 3.45e-12 ***

Height 0.278432 0.009926 28.051 < 2e-16 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 1.056 on 722 degrees of freedom

Multiple R-squared: 0.843, Adjusted R-squared: 0.8425

Call:

 $lm(formula = LungCap \sim Age + Height)$

Residuals:

Min 1Q Median 3Q Max -3.4080 -0.7097 -0.0078 0.7167 3.1679

The test statistic that we use to perform the hypothesis test that the slope for Age = 0.

Coefficients:

Estimate Std. Error t value Pr(>|t|)

(Intercept) -11.747065 0.476899 -24.632 < 2e-16 ***

Age 0.126368 0.017851 7.079 3.45e-12 ***

Height 0.278432 0.009926 28.051 < 2e-16 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 1.056 on 722 degrees of freedom

Call:

 $lm(formula = LungCap \sim Age + Height)$

Residuals:

Min 1Q Median 3Q Max -3.4080 -0.7097 -0.0078 0.7167 3.1679

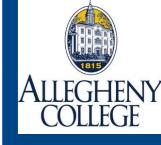

The estimated effect of *Height* on *Lung Capacity*, adjusted for *Age*.

Coefficients:

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 1.056 on 722 degrees of freedom Multiple R-squared: 0.843, Adjusted R-squared: 0.8425

Call:

 $lm(formula = LungCap \sim Age + Height)$

Residuals:

Min 1Q Median 3Q Max -3.4080 -0.7097 -0.0078 0.7167 3.1679

The test statistic that we use to perform the hypothesis test that the slope for *Height* = 0.

Coefficients:

Estimate Std. Error t value Pr(>|t|)

(Intercept) -11.747065 0.476899 -24.632 < 2e-16 ***

Age 0.126368 0.017851 7.079 3.45e-12 ***

Height 0.278432 0.009926 28.051 < 2e-16 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 1.056 on 722 degrees of freedom

Multiple R-squared: 0.843, Adjusted R-squared: 0.8425

ALLEGHENY COLLEGE

R-squared Value:

"How do the independents explain the dependent?"

Call:

 $lm(formula = LungCap \sim Age + Height)$

Residuals:

Min 1Q Median 3Q Max -3.4080 -0.7097 -0.0078 0.7167 3.1679

Approximately 84% of the variation in *Lung Capacity* can be explained by our model (*Age* and *Height*)

Coefficients:

Estimate Std. Error t valv (>|t|)

(Intercept) -11.747065 0.476899 -24 < 2e-16 ***

Age 0.126368 0.017851 379 3.45e-12 ***

Height 0.278432 0.009926 $\angle 8.051 < 2e-16 ***$

Signif. codes: 0 '***' 0.00' '**' 0.01 '*' 0.05 '.' 0.1 ' '1

Residual standard error: 1.056 on 722 degrees of freedom

Multiple R-squared: 0.843, Adjusted R-squared: 0.8425

F-Statistic of Test:

"What value do I look up in a table to check on significance?"

Call:

 $lm(formula = LungCap \sim Age + Height)$

Residuals:

Min 10 Median **3Q** Max -3.4080 -0.7097 -0.0078 0.7167 3.1679

Coefficients:

Estimate Std. Error t value

(Intercept) -11.747065 0.476899 -24.67

0.126368 0.017851 Age 0.278432 0.009926 28 Height

0.05 '.' 0.1 ' '1 0 '***' 0.001 '**' .01 '*' Signif. codes:

Residual standard error: 1.056 o/ 722 degrees of freedom

Multiple R-squared: 0.843, / Adjusted R-squared: 0.8425

F-statistic: 1938 on 2 and 722 DF, p-value: < 2.2e-16

Null Hyp. Test: The test of the null hypothesis that all model coefficients are zero.

Degrees of Freedom: There are 725 rows in the data and three groups.

722 = 725 - 3

Used also for finding values in F-table for hypothesis testing

Our Test of The Null Hypothesis

• Ho:
$$\beta_1 = \beta_2 = ... = \beta_k$$

Nothing is happening between the k-number of variables

In our case,

- Ho:
$$\beta_{age} = \beta_{height} = 0$$
 (slopes are zero)

 y_i

$$= \beta_0 + \beta_1 x_{i,1} + \beta_2 x_{i,2} + \beta_3 x_{i,3} + \epsilon_i$$

```
Call:
```

 $lm(formula = LungCap \sim Age + Height)$

Residuals:

Min 1Q Median 3Q -3.4080 -0.7097 -0.0078 0.7167 3.1

Coefficients:

Estimate Std. Error t

(Intercept) -11.747065 0.476899 -24.

Age 0.126368 0.017851 7.079 2 *** Height 0.278432 0.009926 28.051 5 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0. . .' 0.1 ' ' 1

Residual standard error: 1.056 on 722 degrees of reedom

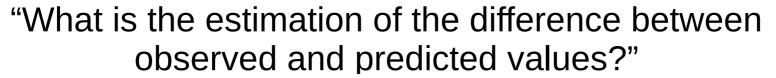

Multiple R-squared: 0.843, Adjusted R-squared 0.8425

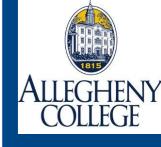

F-statistic: 1938 on 2 and 722 DF, p-value: < 2.2e-16

The p-value is very close to zero and so we reject the Ho (i.e., all the model coefficients are zero (slope = 0).

Conclusion: There is something non-random happening in this model.

Residual Errors:

```
Call:
```

 $lm(formula = LungCap \sim Age + Height)$

Residuals:

Min 1Q Median 3Q Max -3.4080 -0.7097 -0.0078 0.7167 3.1679

This error gives an idea about how far the observed Lung Capacity (dependent) values are from the predicted or fitted Lung Capacity (the "y-hats")

Coefficients:

Estimate Std. Error t value Pr(>|t|)

Age 0.126368 0.017851 7.079 3.45e-12 ***

Height 0.278432 0.009926 28.051 < 2e-16 ***

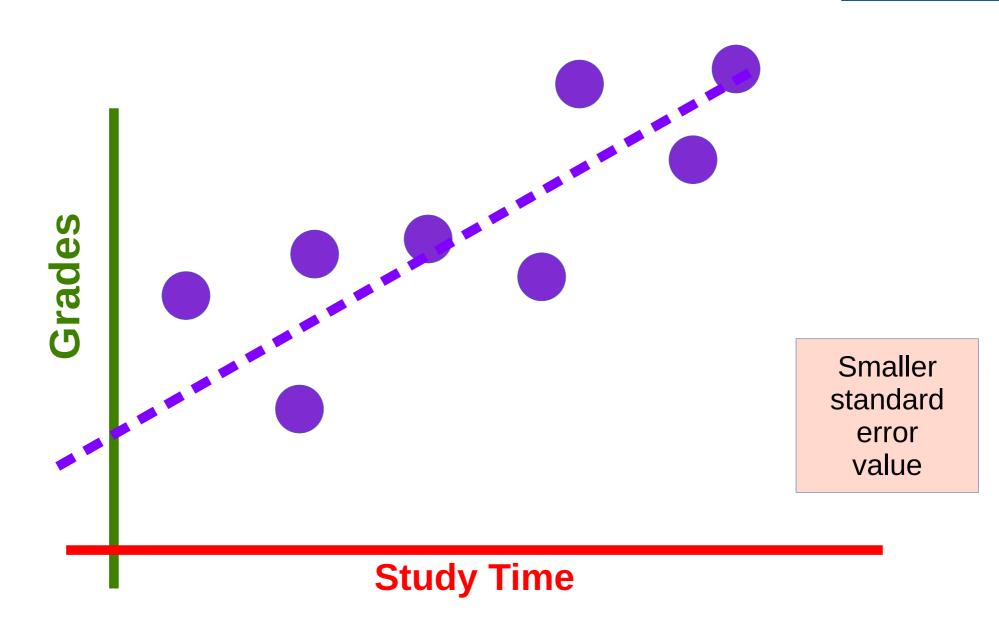

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1

Residual standard error: 1.056 on 722 degrees of freedom

Multiple R-squared: 0.843, Adjusted R-squared: 0.8425

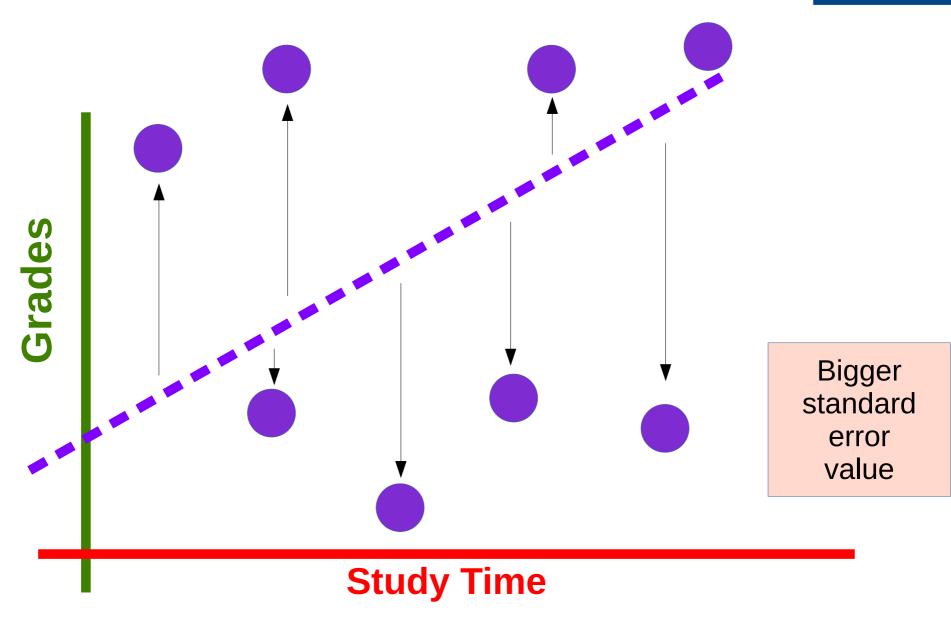

"Good" Residual Standard Error

"Bad" Residual Standard Error

Test for Correlation Between *All* Variables

library(psych)

pairs.panels(dataLungCap)

pairs.panels(dataLungCap, lm = TRUE)

Allows for a quick study of correlation across the variables of your study

pairs.panels {psych}

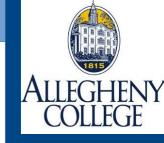

R Documentation

SPLOM, histograms and correlations for a data matrix

Description

Adapted from the help page for pairs, pairs.panels shows a scatter plot of matrices (SPLOM), with bivariate scatter plots below the diagonal, histograms on the diagonal, and the Pearson correlation above the diagonal. Useful for descriptive statistics of small data sets. If Im=TRUE, linear regression fits are shown for both y by x and x by y. Correlation ellipses are also shown. Points may be given different colors depending upon some grouping variable. Robust fitting is done using lowess or loess regression. Confidence intervals of either the Im or loess are drawn if requested.

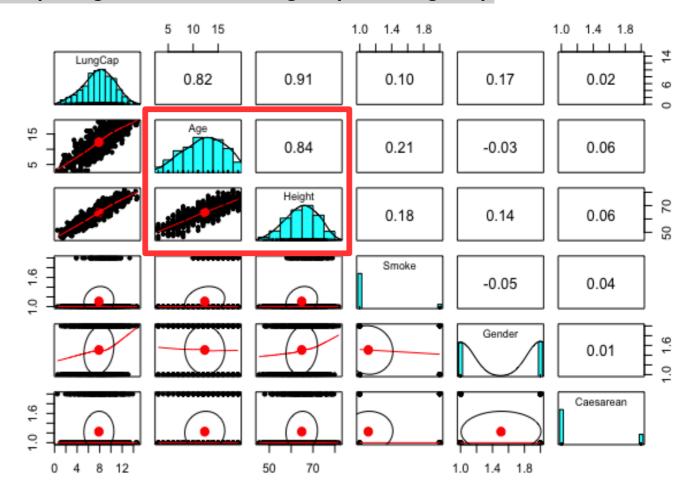

Pearson correlation between Age and Height = 0.84

cor(dataLungCap\$Age, dataLungCap\$Height)

 The high correlation between Age and Height suggests that these two effects are related.

Pearson correlation between Age and Height = 0.84

Correlation and Confidence

```
# Pearson correlation test
cor(dataLungCap$Age, dataLungCap$Height)
# output: 0.8357368
# Examine the 95 percent confidence level
confint(mod, conf.level = 0.95)
```

The **estimated slope** for Age is 0.126 and we are 95 percent sure that the **true slope** of *Age* is between 0.09 and 0.16.

```
> confint(mod, conf.level = 0.95)
2.5 % 97.5 %
(Intercept) -12.68333877 -10.8107918
Age 0.09132215 0.1614142
Height 0.25894454 0.2979192
```

Go Create a Bigger Model!!

- Use this data set to make a bigger model.
- Fit a linear model using ALL x variables.
 Or try a different data set and do more model fitting!

Create Bigger Model!!

- mod2 <- lm(data = dataLungCap, LungCap ~ Age + Height + Smoke + Gender + Caesarean)
- summary(mod2)
- plot(mod2) # check the four plots!
